Building with AI

A one-page guide for anyone using AI builders like Replit, Lovable, or Base44.

Most people jump straight to "build me an app." The AI then guesses everything (who it's for, what it looks like, what it shouldn't do) and the guesses are usually wrong. These three rules fix that.

Rule 1: Set the context BEFORE asking for features

Your **very first message** (the text in yellow) in a new Replit project should not be "build me…". It should be a full spec like the one below, **with photos of your storyboard and POC screens attached.**

Your storyboard and POC are the thinking you do *before* opening Replit: rough sketches of each screen and how they connect, on paper or in Figma. Photos of them carry far more intent than any paragraph of description. Have them ready before you paste.

The bold parts are what you swap with your own app's info. Everything else stays as-is. Paste the whole block as your first message, **attach your storyboard and POC photos,** then wait for the AI to acknowledge before you ask for any features.

Build a **web/native** app called **TuneShare**: **a peer-to-peer marketplace that connects musical instrument owners with musicians who want to rent Instruments.**

I've attached photos of my storyboard and POC screens. Use them as the reference for how each screen should look and how the user moves between them. The text below covers features, monetization, branding, and what NOT to build.

Core features:
- **Google login for sign-up**
- **Two user roles: Owners (list instruments) and Renters (browse and rent). A user can be both.**
- **Listings: Owners post instruments with photos, description, category (guitar, piano, drums, brass, strings), condition, hourly/weekly price, and pickup city**
- **Location matching: show renters the closest instruments first**
- **Booking & calendar: renters pick rental dates; show availability**
- **Handover flow: both parties confirm pickup and return**
- **Payments via Stripe, with a refundable deposit held until return**
- **In-app chat between owners and renters to coordinate handover**
- **Reviews and ratings for both sides after a completed rental**

Monetization:

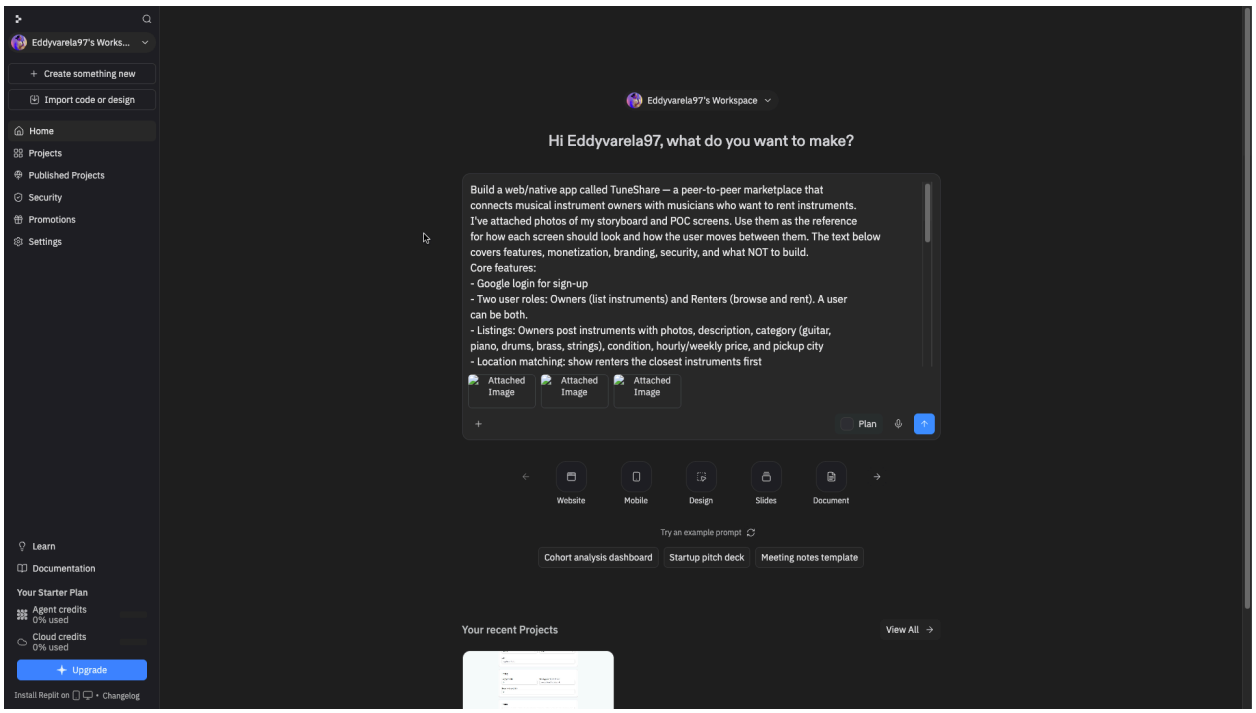

- Revenue model: 10% platform commission on every completed rental, deducted before payout to the owner.
- Refundable security deposit (amount set per listing) held by the platform until the return is confirmed.
- No subscription tiers in v1 — pay-per-rental only. (If your app has plans, list each tier here: name, price, what's included.)

Branding & design:
- App name: **TuneShare**
- UI: keep it generic and functional with Tailwind UI. Use the AI builder's default look, no custom logos, colors, or fonts. (Branding will come later, in a separate prompt)

Security:
Build this like a real app, keep secret keys (Stripe, DB, login) on the server, never in browser code; verify all user input and permissions on the server, not the client; stop and ask me if a step feels risky.

Don't add: **extra logins beyond Google, ads, long sign-up forms, paid tiers, dark mode toggle**

If anything is unclear, ask me before building.

This is what it looks like in Replit: paste the prompt in the message box, then attach your storyboard and POC Screens

Then (and only then) ask for the first feature, one at a time.

Why this works: you only say it once. Every feature you ask for afterwards inherits this context. Without it, every prompt can confuse the AI.

Rule 2 — When it's wrong, fix the rules, not the output

It's tempting to keep arguing with the AI about the same screen. That's a trap! you'll have the same fight on the next screen, and the next.

The trap looks like this:

> **You:** make the button bigger
> **AI:** *regenerates*
> **You:** no, bigger
> **AI:** *regenerates*
> **You:** no, more rounded
> **AI:** *regenerates*
> *Next screen it makes, the buttons are small and square again.*

The fix: add a rule instead of arguing:

> **You:** Add this to your context and apply it from now on: *all buttons must be at least 48px tall and have rounded corners.* Then redo this screen.
> **AI:** ✅
> *Every future screen has tall, rounded buttons. For free.*

A few rules people commonly end up needing:

- "Never use red, it looks like an error."
- "Always show prices with the currency symbol."
- "When something succeeds, say it in plain language, not 'Success.'"
- "Forms have at most 3 fields per screen."

> The output is the symptom. The rules are the cause. Fix the cause.

Rule 3: Keep a tiny "lessons" note

Open a google doc called **Lessons**. Every time you find a rule you wish you'd had on day one, write one line.

Examples:

"I have to tell the AI who the user is every time."
"I ask for the mobile view first, because it's the harder constraint."
"'Make it cool' gives me random results. Two-three specific words work better."
"If I don't say what NOT to add, the AI adds it by default."

Next project, paste your lessons into Rule 1 from day one. Your context gets smarter, the AI gets sharper, and you stop repeating the same fights with yourself.

The whole loop in one sentence

Set the context → ask for features one at a time → if it's wrong, fix the rules not the output → write down what you learned.

That's it.

Feedback:

- AI expenses went over $100 USD
- Context rot, conversation gets accumulated with unuseful info. New chats are needed
- Architecture file is needed
- Better prompting lessons to students
- Error messages are too generic on the UI of the students apps
